Only hyperuricemia with crystalluria but not asymptomatic hyperuricemia drives progression of chronic kidney disease

JASN
JOURNAL OF THE AMERICAN SOCIETY OF NEPHROLOGY

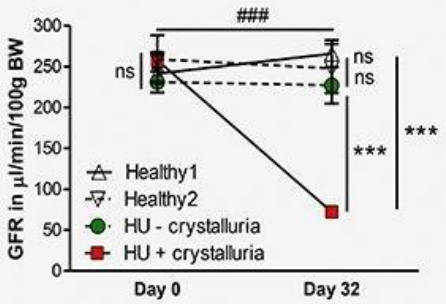
Methods

Mouse models:
- Aristolochic acid I-induced nephropathy
- Asymptomatic hyperuricemia without crystalluria
- Chronic uric acid crystal nephropathy with granulomatous nephritis

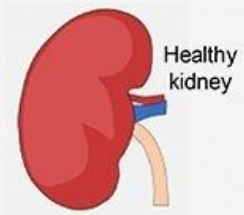
Serum uric acid

5.3±0.5 mg/dl	15.6±3.2 mg/dl	16.0±2.5 mg/dl
***Glut9*lox/lox control**	**Alb-creERT2; *Glut9*lox/lox**	**Alb-creERT2; *Glut9*lox/lox**
		Urinary pH 6.9	Urinary pH 6.8	Urinary pH 5.2

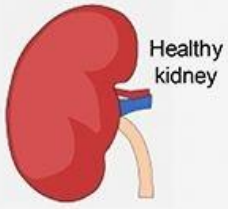
Results



Healthy



Asympt. hyperuricemia without crystalluria



Hyperuricemia with crystalluria-induced CKD + granuloma formation

No impact of hyperuricemia (sUA 16 mg/dl) on pre-existing aristolochic acid I-induced nephropathy.

Conclusion

Asymptomatic hyperuricemia does not affect CKD progression unless uric acid crystallizes in the kidney, leading to tubular obstruction, inflammation, and interstitial fibrosis. Subsequently, uric acid crystal granulomas form, a process mediated by proinflammatory M1-like macrophages, and contribute to CKD progression.

Uric acid crystal granulomas consist of proinflammatory M1-like macrophages

Table 1 Overarching principles and final set of 11 recommendations for the treatment of gout

	Overarching principles
A	Every person with gout should be fully informed about the pathophysiology of the disease, the existence of effective treatments, associated comorbidities and the principles of managing acute attacks and eliminating urate crystals through lifelong lowering of SUA level below a target level.
B	Every person with gout should receive advice regarding lifestyle: weight loss if appropriate and avoidance of alcohol (especially beer and spirits) and sugar-sweetened drinks, heavy meals and excessive intake of meat and seafood. Low-fat dairy products should be encouraged. Regular exercise should be advised.
C	Every person with gout should be systematically screened for associated comorbidities and cardiovascular risk factors, including renal impairment, coronary heart disease, heart failure, stroke, peripheral arterial disease, obesity, hyperlipidaemia, hypertension, diabetes and smoking, which should be addressed as an integral part of the management of gout.
	Final set of 11 recommendations
1	Acute flares of gout should be treated as early as possible. Fully informed patients should be educated to self-medicate at the first warning symptoms. The choice of drug (s) should be based on the presence of contraindications, the patient's previous experience with treatments, time of initiation after flare onset and the number and type of joint(s) involved.
2	Recommended first-line options for acute flares are colchicine (within 12 hours of flare onset) at a loading dose of 1 mg followed 1 hour later by 0.5 mg on day 1 and/or an NSAID (plus proton pump inhibitors if appropriate), oral corticosteroid (30–35 mg/day of equivalent prednisolone for 3–5 days) or articular aspiration and injection of corticosteroids. Colchicine and NSAIDs should be avoided in patients with severe renal impairment. Colchicine should not be given to patients receiving strong P-glycoprotein and/or CYP3A4 inhibitors such as cyclosporin or clarithromycin.
3	In patients with frequent flares and contraindications to colchicine, NSAIDs and corticosteroid (oral and injectable), IL-1 blockers should be considered for treating flares. Current infection is a contraindication to the use of IL-1 blockers. ULT should be adjusted to achieve the uricaemia target following an IL-1 blocker treatment for flare.
4	Prophylaxis against flares should be fully explained and discussed with the patient. Prophylaxis is recommended during the first 6 months of ULT. Recommended prophylactic treatment is colchicine, 0.5–1 mg/day, a dose that should be reduced in patients with renal impairment. In cases of renal impairment or statin treatment, patients and physicians should be aware of potential neurotoxicity and/or muscular toxicity with prophylactic colchicine. Co-prescription of colchicine with strong P-glycoprotein and/or CYP3A4 inhibitors should be avoided. If colchicine is not tolerated or is contraindicated, prophylaxis with NSAIDs at low dosage, if not contraindicated, should be considered.
5	ULT should be considered and discussed with every patient with a definite diagnosis of gout from the first presentation. ULT is indicated in all patients with recurrent flares, tophi, urate arthropathy and/or renal stones. Initiation of ULT is recommended close to the time of first diagnosis in patients presenting at a young age (<40 years) or with a very high SUA level (>8.0 mg/dL; 480 μmol/L) and/or comorbidities (renal impairment, hypertension, ischaemic heart disease, heart failure). Patients with gout should receive full information and be fully involved in decision-making concerning the use of ULT.
6	For patients on ULT, SUA level should be monitored and maintained to <6 mg/dL (360 μmol/L). A lower SUA target (<5 mg/dL; 300 μmol/L) to facilitate faster dissolution of crystals is recommended for patients with severe gout (tophi, chronic arthropathy, frequent attacks) until total crystal dissolution and resolution of gout. SUA level <3 mg/dL is not recommended in the long term.
7	All ULTs should be started at a low dose and then titrated upwards until the SUA target is reached. SUA <6 mg/dL (360 μmol/L) should be maintained lifelong.
8	In patients with normal kidney function, allopurinol is recommended for first-line ULT, starting at a low dose (100 mg/day) and increasing by 100 mg increments every 2–4 weeks if required, to reach the uricaemia target. If the SUA target cannot be reached by an appropriate dose of allopurinol, allopurinol should be switched to febuxostat or a uricosuric or combined with a uricosuric. Febuxostat or a uricosuric are also indicated if allopurinol cannot be tolerated.
9	In patients with renal impairment, the allopurinol maximum dosage should be adjusted to creatinine clearance. If the SUA target cannot be achieved at this dose, the patient should be switched to febuxostat or given benzbromarone with or without allopurinol, except in patients with estimated glomerular filtration rate <30 mL/min.
10	In patients with crystal-proven, severe debilitating chronic tophaceous gout and poor quality of life, in whom the SUA target cannot be reached with any other available drug at the maximal dosage (including combinations), pegloticase is indicated.
11	When gout occurs in a patient receiving loop or thiazide diuretics, substitute the diuretic if possible; for hypertension consider losartan or calcium channel blockers; for hyperlipidaemia, consider a statin or fenofibrate.

IL, interleukin; NSAID, non-steroidal anti-inflammatory drug; SUA, serum uric acid; ULT, urate-lowering therapy.

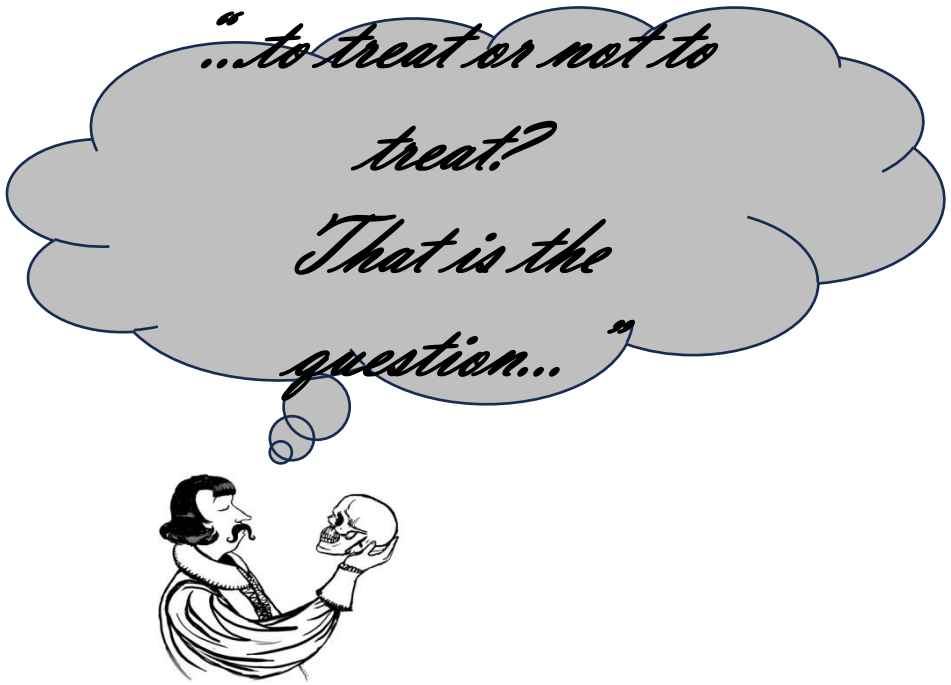
Sriperumbuduri & Hiremath
Curr Opin Nephrol Hypertens 2019

AMERICAN COLLEGE OF RHEUMATOLOGY

Initiating ULT is conditionally recommended *against* in patients with gout experiencing their first gout flare.

However, initiating ULT is conditionally recommended for patients with comorbid moderate-to-severe CKD (stage ≥3), SU concentration >9 mg/dl, or urolithiasis.

FitzGerald et al. Arthritis Rheumatol 2020



5. *ULT should be considered and discussed with every patient with a definite diagnosis of gout from the first presentation. ULT is indicated in all patients with recurrent flare (≥2/year), tophi, urate arthropathy and/or renal stones. Initiation of ULT is recommended close to the time of first diagnosis in patients presenting at a young age (<40 years), or with a very high SUA level (>8 mg/dL; 480 μmol/L) and/or comorbidities (renal impairment, hypertension, ischaemic heart disease, heart failure). Patients with gout should receive full information and be fully involved in decision-making concerning the use of ULT.*

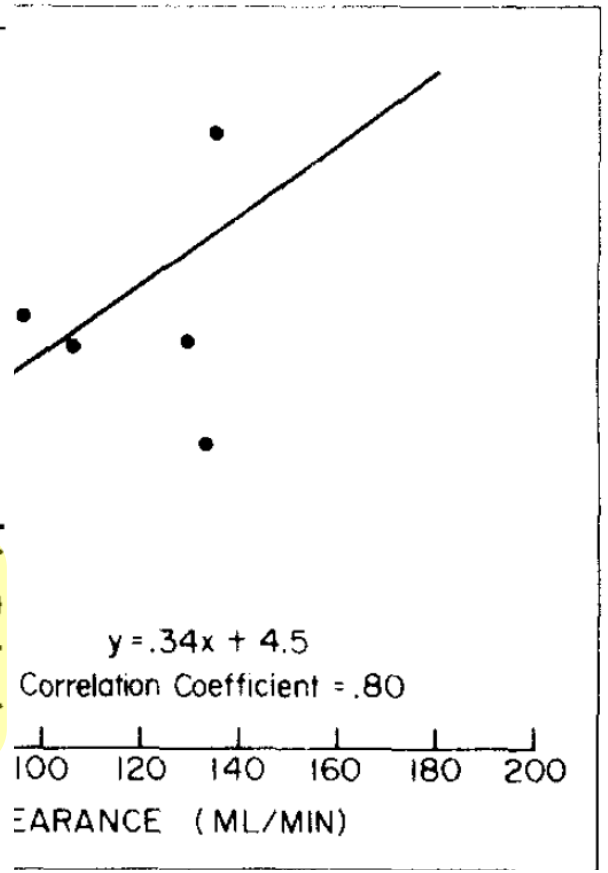
Concomitant diuretic therapy	

TABLE IV **Maintenance Doses of Allopurinol for Adults Based on Individual Creatinine Clearance Measurements**

Creatinine Clearance (ml per minute)	Maintenance Dose of Allopurinol
0	100 mg every three days
10	100 mg every two days
20	100 mg daily
40	150 mg daily
60	200 mg daily
80	250 mg daily
100	300 mg daily
120	350 mg daily
140	400 mg daily

This table is based on a standard maintenance dose of 300 mg per day of allopurinol for a patient with a creatinine clearance of 100 ml per minute. The suggested maintenance doses of allopurinol for patients with other creatinine clearances are based on the maintenance dose ratio, where:

Renal insufficiency dose/Standard dose = Serum oxipurinol half-life oxipurinol at creatinine clearance of 100 ml per minute/Serum oxipurinol half-life oxipurinol in renal insufficiency



Hande et al. Am J Med 1984

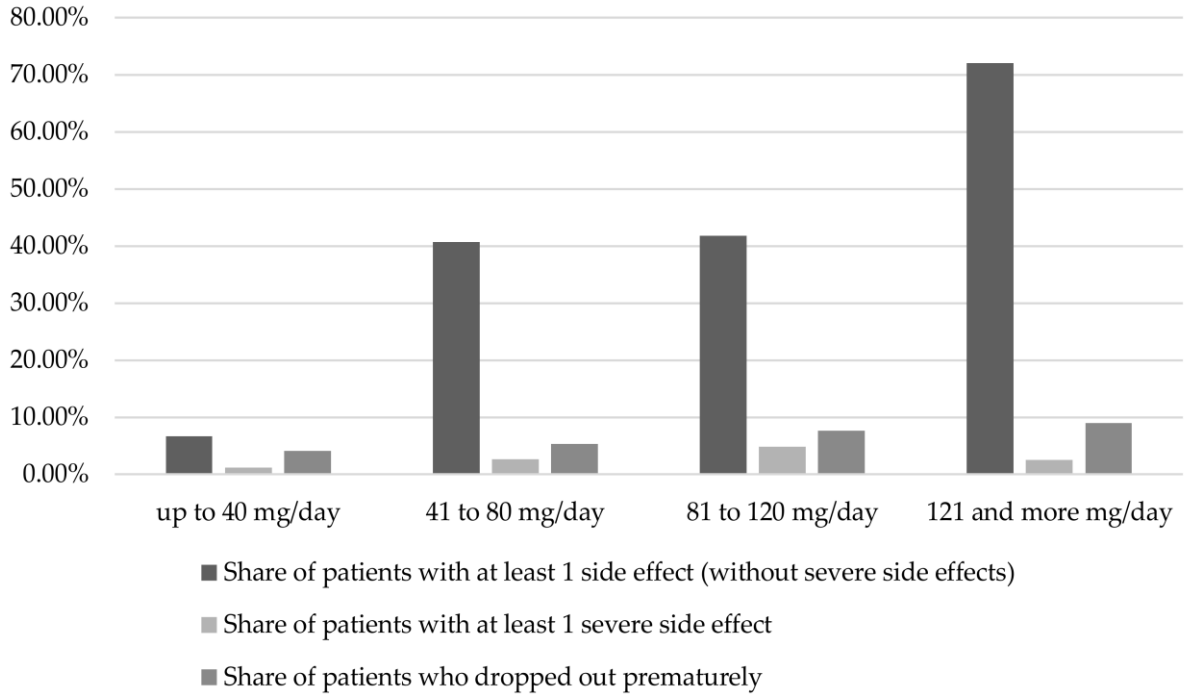
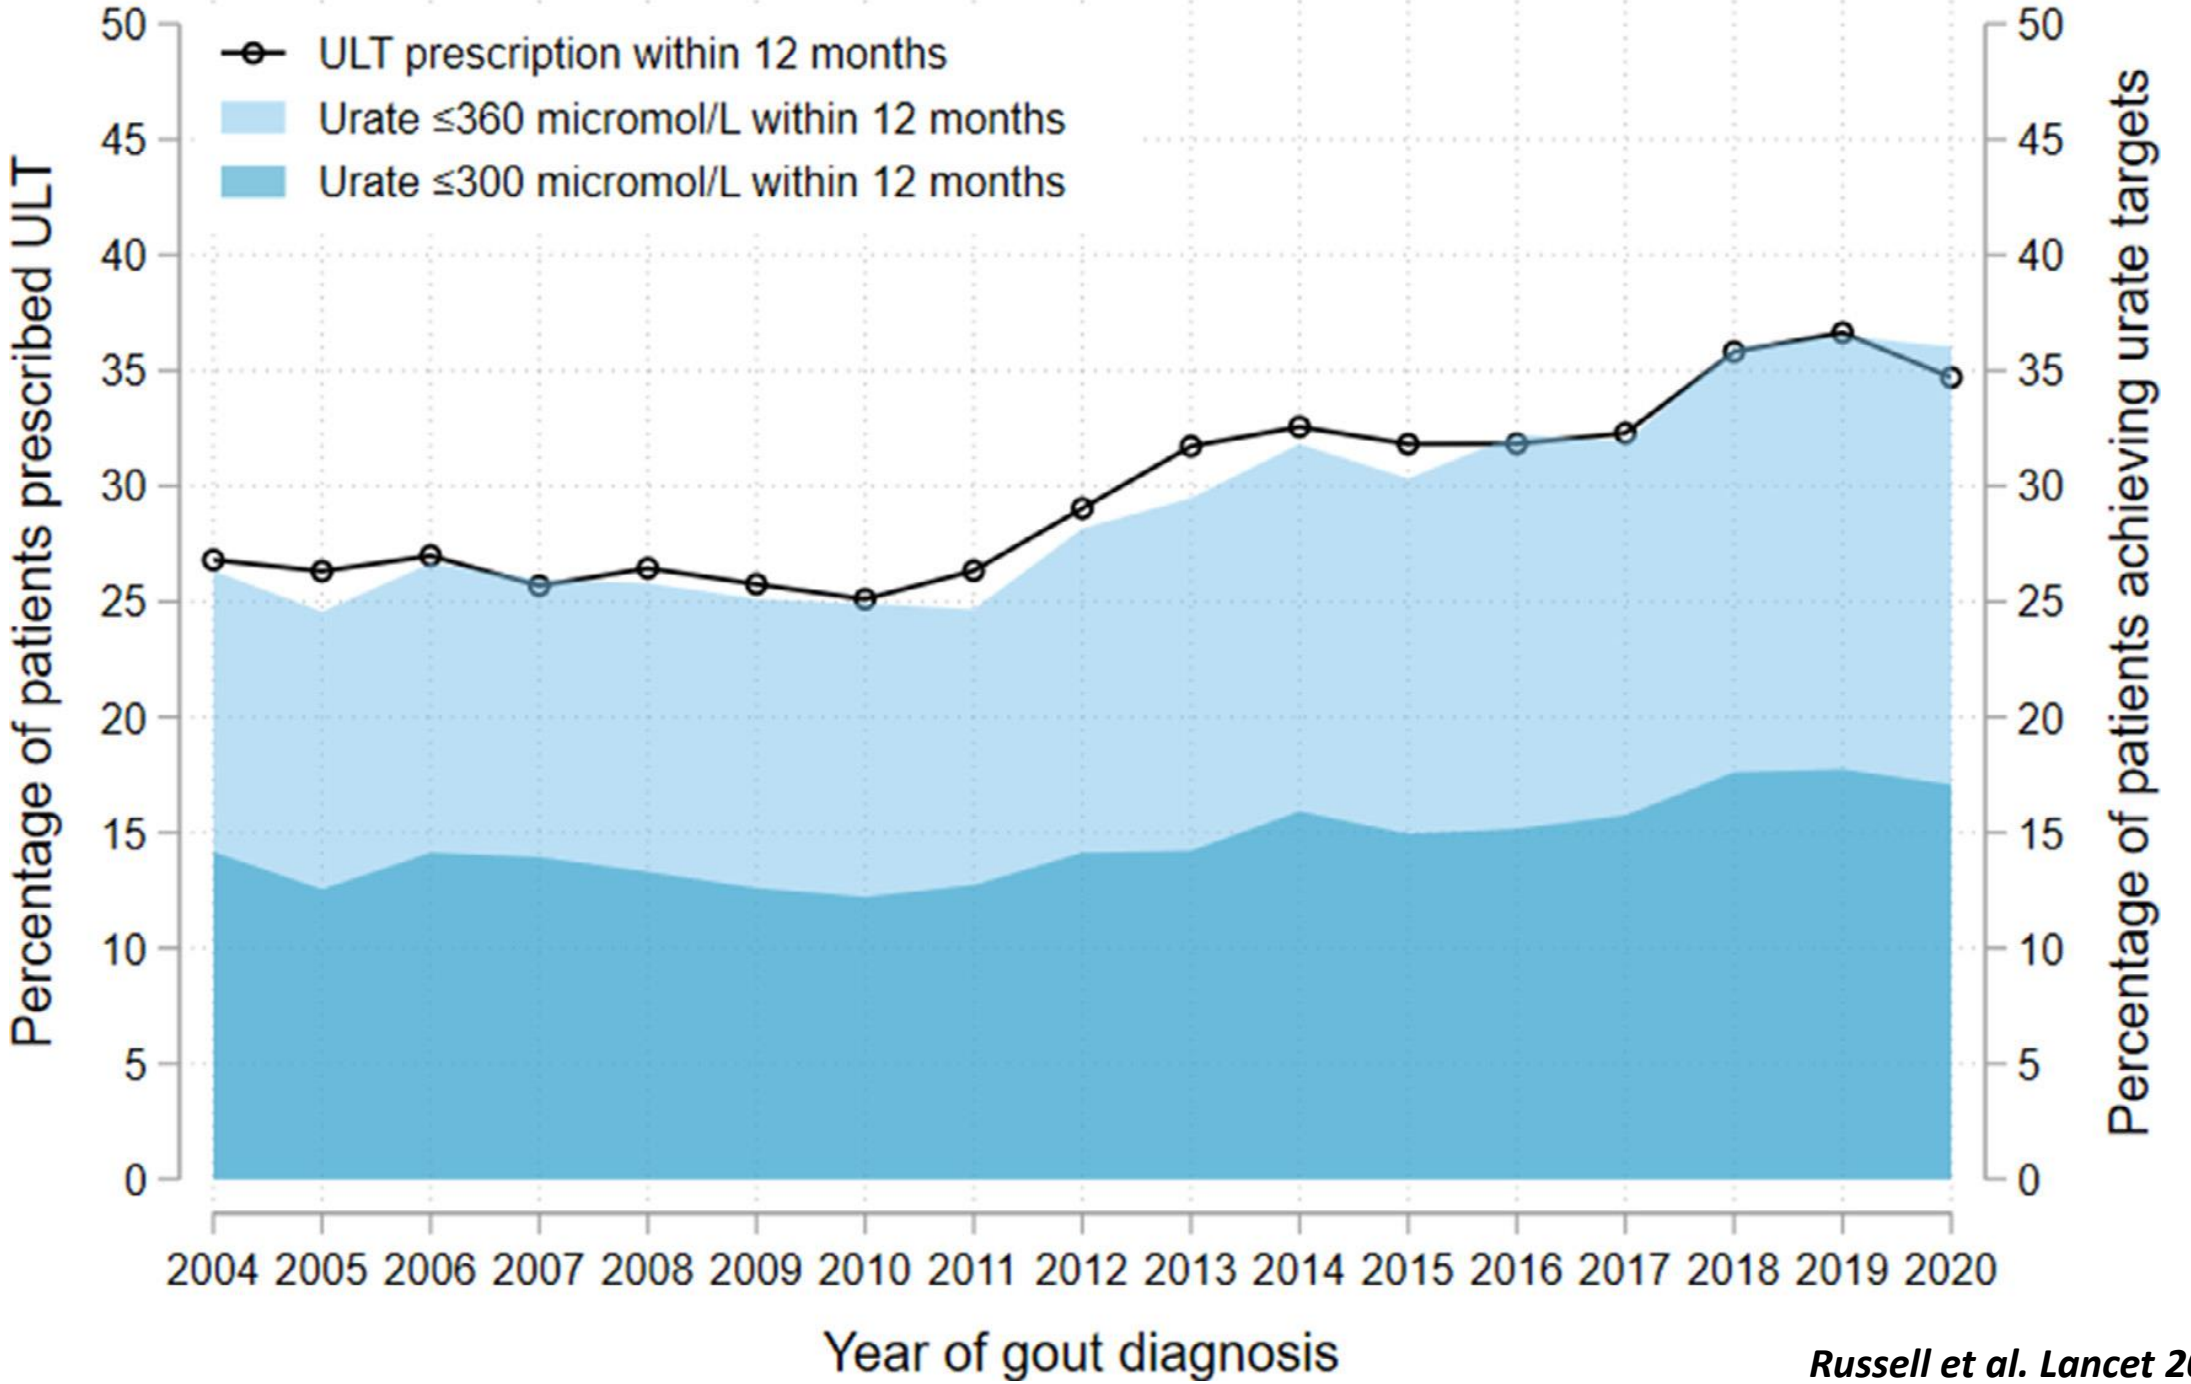
N=5037



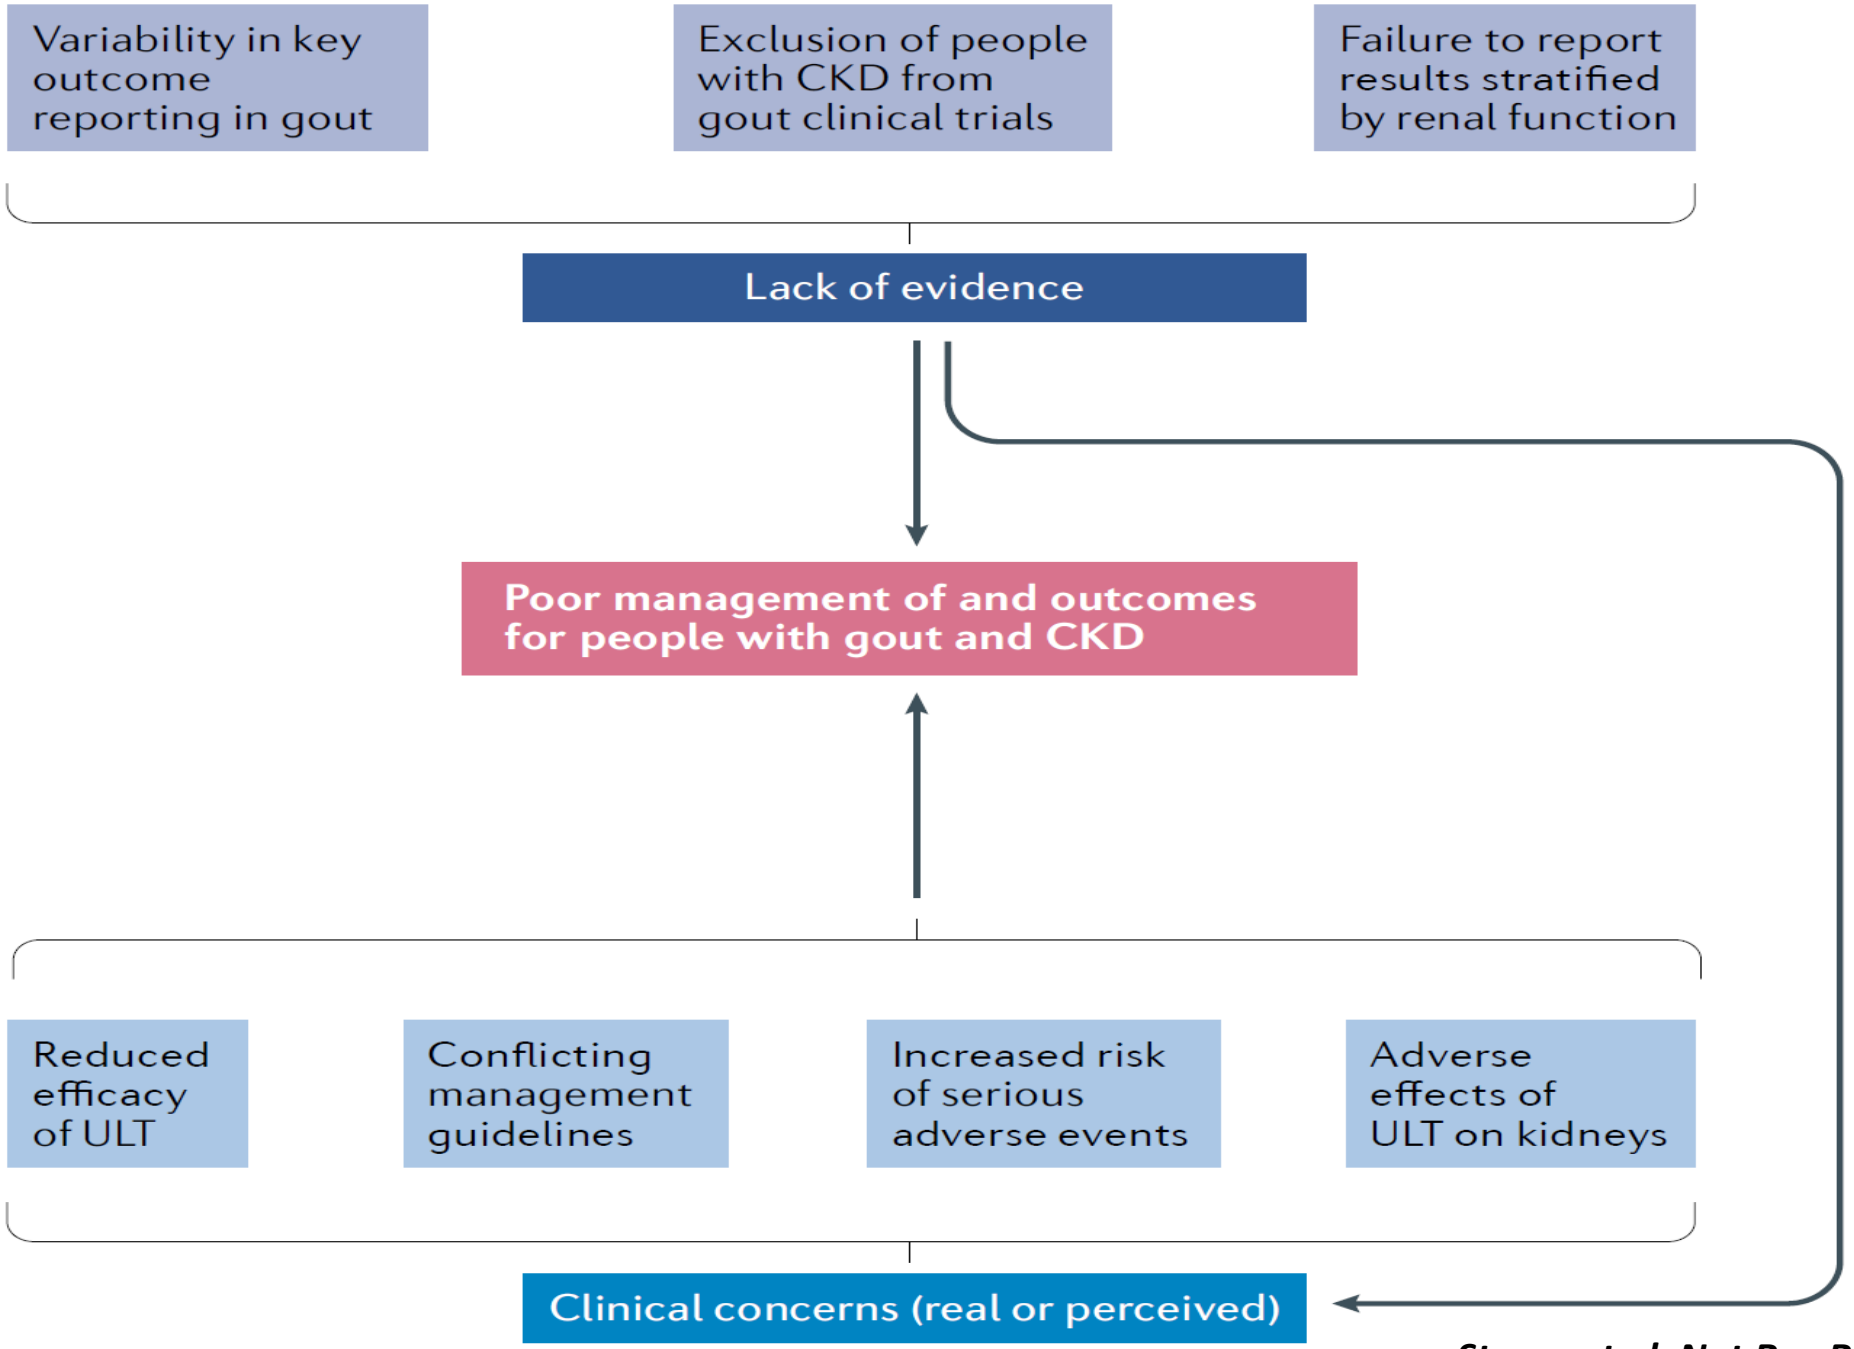
AMERICAN COLLEGE OF RHEUMATOLOGY

Starting treatment with low-dose allopurinol (≤100 mg/day and lower in patients with CKD [stage ≥3]) and febuxostat (≤40 mg/day) with subsequent dose titration over starting at a higher dose is strongly recommended.

Jordan & Gresser. Pharmaceuticals 2018



Russell et al. Lancet 2022



Stamp et al. Nat Rev Rheumatol 2021

Urate-Lowering Agents	Doses	Recommendations for CKD 3-5	Recommendations for CKD 5D (dialysis)
		XOIs[a]	
Allopurinol	Starting: 50-100 mg/d; maximal approved: 800 mg/d (900 mg/d in the UK)	$CL_{cr} \geq 30$ mL/min: start with ≤ 100 mg/d[18] $CL_{cr} < 30$ mL/min: start with 50 mg/d[18]	Intermittent HD: should be administered postdialysis,[26,27] start with 100 mg alternate days postdialysis Daily HD: additional 50% of dose may be required postdialysis Daily PD: start with 50 mg/d All types of RRT: uptitrate dose with 50-mg increments every 2-5 wk, measure serum urate predialysis
Febuxostat	Starting: 40 mg/d; maximal approved: 80 mg/d (120 mg/d in Europe)	Insufficient data for $CL_{cr} < 30$ mL/min	Despite some successful reports of dialysis patients using febuxostat up to 80 mg/d, this agent is not FDA approved for use in dialysis due to a lack of trials in this population[28-32]
		Uricosuric Agents[b]	
Benzbromarone[c]	Starting: 25-50 mg/d; maximal approved: 200 mg/d	Contraindicated if $CL_{cr} < 20$ mL/min	Contraindicated
Lesinurad[d]	Starting: 200 mg/d together with XOI; maximal approved: 200 mg/d	Contraindicated if $CL_{cr} < 45$ mL/min	Contraindicated
Probenecid	Starting: 250 mg twice daily; maximal approved: 2,000 mg/d	Not effective if $CL_{cr} \leq 30$ mL/min	Contraindicated
Sulfinpyrazone[c]	Starting: 50 mg twice daily; maximal approved: 800 mg/d	Not effective if $CL_{cr} \leq 30$ mL/min	Contraindicated
		Recombinant Uricase	
Pegloticase	Starting: 8 mg IV every 2 wk; maximal approved: 8 mg IV every 2 wk	No dose adjustment needed	No dose adjustment needed[33]

Vargas-Santos & Neogi. Am J Kidney Dis 2017

In a US population-based study, the prevalence of CKD (stage ≥2) in patients with SUA level ≥10 mg/dL (594.9 µmol/L) and in patients with gout was 86% and 53%, respectively. CKD appears to be a major risk factor for gout and, conversely, gout might cause renal dysfunction.[53] [54] The task force agreed that identifying CKD in patients with gout was of major importance because of the therapeutic implications, as discussed in items 1, 2, 4, 5, 8 and 9. Therefore, estimated glomerular filtration rate (eGFR) should be calculated at the time of diagnosis for CKD classification and monitored regularly in parallel with SUA measurement. This item also emphasises the need to search for other important associated comorbidities, especially coronary

Y: 50♂
W:80kg
H:180cm
Cr:1.35mg/dl

MDRD – eGFR: 55.9 mL/min/1.73m²

CKD-EPI – eGFR: 64 mL/min/1.73m²

Y: 50♂
W:50kg

MDRD – eGFR: 55.4 mL/min/1.73m²

CKD-EPI – eGFR: 64 mL/min/1.73m²

eGFR Calculator

Glomerular filtration rate (GFR) is the best overall index of kidney function. Normal GFR varies according to age, sex, and body size, and declines with age. The National Kidney Foundation recommends using the CKD-EPI Creatinine Equation (2021) to estimate GFR. More information regarding this recommendation may be found here.

NKF and the American Society of Nephrology have convened a Task Force to focus on the use of race to estimate GFR. *Read more about the task force here.*
